Amazon Relational Database Service (RDS):

1. Using boto, we need to create an RDS instance. Take ‘mysql’ as the database engine. We need to wait for a few minutes so that the RDS instance becomes running.
2. We need to create a feedback table in RDS.
3. We need to note the security group and endpoint of the RDS instance.
4. In the security group, add an inbound rule for port 3306. It is needed for mysql. (If we can not connect to the RDS endpoint, we can add an inbound rule for all traffic.)
5. Connect to the RDS endpoint from the terminal.
   mysql -h <your-rds-endpoint-name> -P 3306 -u your-username -p
6. We can create a Flask application (in Python) for a feedback table. In the Flask application, we can give the RDS endpoint as a parameter.
7. Take necessary screenshots. Delete the **RDS instance** after your work is done.
